## Arrays

- ⌘ A one-dimensional array is an ordered list of elements, all of the same type.
- ⌘ To define an array in assembly language
  - ⊞ `W            dw    10,20,30,40,50,60`
- ⌘ The address of the array variable is called the base address of the array
- ⌘ If the offset address of the array is 0200h, the array looks like this in memory:

element	offset	address	symbolic address	contents
W[0]		0200h	W	10
W[1]		0202h	W+2h	20
W[2]		0204h	W+4h	30
W[3]		0206h	W+6h	40

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

2

# The TIMES Operator

⌘ Arrays whose elements share a common initial value are defined using the TIMES pseudo-op

⌘ It has the form:

⏏ **TIMES** *repeat\_count* *directive*

⌘ **gamma TIMES 100 dw 0**

⏏ sets up an array of 100 words, with each entry initialized to 0

⌘ For uninitialized data we use the **resb** directive:

⏏ **delta resb 212**

⏏ sets up an array of 212 uninitialized bytes

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

3

# Location of Array Elements

⌘ The address of an array element may be computed by adding a constant to the base address

⌘ If A is an array and S denotes the number of bytes in an element, then the address of element A[i] is  $A + i \cdot S$  (assuming zero-based arrays; for one-based arrays it would be  $A + (i-1) \cdot S$ )

⌘ To exchange W[9] and W[24] in an word array W:

**mov ax, [W+18] ; ax has W[9]**

**xchg [W+48], ax ; ax has W[24]**

**mov [W+18], ax ; complete exchange**

4

# Addressing Data in Memory

⌘ Three forms:

☒ Immediate data -- stored directly in machine code

☒ example: `mov ax, 5` ; 5 is an immediate value

☒ immediate operands are always source operands

☒ Register data -- held in processor registers

☒ example: `add ax, bx`

☒ Memory data -- held in memory

☒ processor calculates the 16-bit effective address

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

5

# Memory-Addressing Modes

Direct	<code>mov ax, count</code>
Register-indirect	<code>mov ax, [bx]</code>
Base	<code>mov ax, [record + bp]</code>
Indexed	<code>mov ax, [array + si]</code>
Base-indexed	<code>mov ax, [recordArray + bx + si]</code>
String	<code>lodsw</code>
I/O Port	<code>in ax, dx</code>

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

6

## Direct Addresses

⌘ Direct address references are usually relative to **ds**

⌘ To change this, use a *segment override*:

⌘ `mov ch, es:OverByte`

⌘ Other segment bases are possible:

⌘ `mov dh, cs:CodeByte`

⌘ `mov dh, ss:StackByte`

⌘ `mov dh, ds:DataByte`

⌘ An override occupies a byte of machine code which is inserted just before the affected instruction

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

7

## Register-Indirect Mode

⌘ The offset address of the operand is contained in a register

⌘ The register acts as a *pointer* to the memory location

⌘ The operand format is

⌘ `[register]`

⌘ The register is **bx**, **si**, **di**, or **bp**

⌘ For **bx**, **si**, or **di**, the segment register is **ds**

⌘ For **bp**, **ss** has the segment number

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

8

## Example

⌘ **si** = 0100h, [0100h] = 1234h

⌘ To execute **mov ax,[si]** the CPU

☐ examines **si** and obtains the offset address **0100h**

☐ uses the address **ds:0100h** to obtain the value  
**1234h**

☐ moves **1234h** into **ax**

⌘ This is not the same as **mov ax,si** which simply moves the value of **si** (0100h) into **ax**

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

9

## Another example

**bx**=1000h, **si**=2000h, **di**=3000h, [1000h]=1BACH,  
[2000h]=20FEh, [3000h]=031Dh

instruction	source offset	result
<b>mov bx,[bx]</b>	<b>1000h</b>	<b>1BACH</b>
<b>mov cx,[si]</b>	<b>2000h</b>	<b>20FEh</b>
<b>mov bx,[ax]</b>	<i>illegal source register</i>	
<b>add [si],[di]</b>	<i>illegal memory-memory add</i>	
<b>inc word [di]</b>	<b>3000h</b>	<b>031Eh</b>

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

10

# Processing Arrays using Register-Indirect Mode

⌘ Sum in ax the 10-element word array W

W      dw      10,20,30,40,50,60,70,80,90,10

```

        xor    ax,ax        ; ax holds sum
        mov    si,W         ; si points to array W
        mov    cx,10        ; cx has number of elements
addnos:
        add    ax,[si]      ; sum = sum + element
        add    si,2         ; move pointer to the next
                           ; element
        loop   addnos       ; loop until done
```

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

11

# WORD and BYTE operators

⌘ Both operands of an instruction must be of the same type

☒ `mov ax,1` is a word operation because `ax` is a 16-bit register

☒ `mov bh,5` is a byte operation

☒ `mov [bx],1` is illegal because the assembler can't tell whether the destination is a byte or a word

⌘ if you want the destination to be a byte, use

```
mov BYTE [bx],1
```

⌘ and if you want it to be a word, use

```
mov WORD [bx],1
```

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

12

## Based and Indexed Addressing Modes

- ⌘ The operands offset address is obtained by adding a number called a *displacement* to the contents of a register
- ⌘ The displacement may be:
  - ☒ the offset address of a variable, *e.g.*, **A**
  - ☒ a constant, *e.g.*, **-2**
  - ☒ the offset address of a variable plus or minus a constant, *e.g.*, **A + 4**

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

13

## Syntax of an operand

- ⌘ Any of the following expressions are equivalent:
  - ☒ `[register + displacement]` ← *preferred form*
  - ☒ `[displacement + register]`
  - ☒ `[register] + displacement`
  - ☒ `displacement + [register]`
  - ☒ `displacement[register]`
- ⌘ The register must be **bx**, **bp**, **si**, or **di**.
- ⌘ If **bx**, **si**, or **di** is used, **ds** contains the segment number
- ⌘ If **bp** is used, **ss** has the segment number
- ⌘ The addressing is called **based** if **bx** or **bp** is used; it is called **indexed** if **si** or **di** is used

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

14

## Application of Index Mode

⌘ Replace the lowercase letters in the string to uppercase using index addressing mode

```
msg      db      "this is a message"
          mov     cx,17          ; # chars in string
          xor     si,si          ; si indexes a char
top:      cmp     [si+msg],' '    ; blank?
          je      next          ; yes, skip over
          and     [si+msg],0DFh   ; no, convert to upper
next:     inc     si             ; index next byte
          loop    top            ; loop until done
```

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

15

## Processing Arrays using Based Addressing Mode

⌘ Sum in ax the 10-element word array W using based mode

```
W        dw      10,20,30,40,50,60,70,80,90,10

          xor     ax,ax          ; ax holds sum
          xor     bx,bx          ; clear base register
          mov     cx,10          ; cx has number of elements
addnos:   add     ax,[bx+W]       ; sum = sum + element
          add     bx,2           ; index next element
          loop    addnos         ; loop until done
```

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

16

## Base-Indexed Addressing Mode

- ⌘ In this mode the offset address is the sum of:
  - ⊠ the contents of a base register (**bx** or **bp**)
  - ⊠ the contents of an index register (**si** or **di**)
  - ⊠ optionally, a variable's offset address
  - ⊠ optionally, a positive or negative constant
- ⌘ There are many valid ways to write the operand, some of them are:
  - ⊠ `[base + index + variable + constant]` ← *preferred*
  - ⊠ `variable[base + index + constant]`
  - ⊠ `constant[base + index + variable]`

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

17

## Use of Based, Indexed, and Base-Indexed Modes

- ⌘ Based and indexed addressing mode is often used for array and string processing
- ⌘ Based-indexed addressing mode can be used for two dimensional arrays
- ⌘ We will discuss these in greater detail later

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

18

## LEA vs. MOV

⌘ `lea ax,[data]`

and

`mov ax, data`

do the same thing, but the `mov` is more efficient

⌘ However,

`lea bx,[A + si]`

is more efficient than

`mov bx, A`

`add bx, si`

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

19

## Two-Dimensional Arrays

⌘ A 2D array is an array of arrays

⌘ Usually view them as consisting of rows and columns

`A[0,0]`   `A[0,1]`   `A[0,2]`   `A[0,3]`

`A[1,0]`   `A[1,1]`   `A[1,2]`   `A[1,3]`

`A[2,0]`   `A[2,1]`   `A[2,2]`   `A[2,3]`

⌘ Elements may be stored in row-major order or column-major order

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

20

## Locating an Element in a 2D Array

- ⌘ A is an  $M \times N$  array in row-major order, where the size of the elements is  $S$
- ⌘ To find the location of  $A[i,j]$ 
  - ☐ find where row  $i$  begins
  - ☐ find the location of the  $j^{\text{th}}$  element in that row
- ⌘ Row 0 begins at location  $A$  -- row  $i$  begins at location  $A + i \cdot N \cdot S$
- ⌘ The  $j^{\text{th}}$  element is stored  $j \cdot S$  bytes from the beginning of the row
- ⌘ So,  $A[i,j]$  is in location  $A + (i \cdot N + j) \cdot S$

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

21

## 2D Arrays and Based-Indexed Addressing Mode

- ⌘ Suppose  $A$  is a  $5 \times 7$  word array stored in row-major order. Write code to clear row 2.

```
mov  bx,28          ; bx indexes row 2
xor   si,si         ; si will index columns
mov   cx,7          ; # elements in a row
clear: mov [bx + si + A],0 ; clear A[2,j]
      add  si,2      ; go to next column
      loop clear     ; loop until done
```

Copyright 2001-14 by Timothy J. McGuire, Ph.D.

22

## Another Example:

⌘ Write code to clear column 3 -- Since A is a 7 column word array we need to add  $2*7 = 14$  to get to the next row

```
      mov  si,6           ; si indexes column 3
      xor  bx,bx          ; bx will index rows
      mov  cx,5           ; #elements in a column
clear: mov  [bx + si + A],0 ; clear A[i,3]
      add  bx,14          ; go to next row
      loop clear          ; loop until done
```
